

**Applied Statistics Comprehensive Examination
Regression & Linear Models**

1. (40 Points) Consider the following main effects model without replicates:

$$y_{ij} = \mu + \alpha_i + \beta_j + \epsilon_{ij}$$

where Factor A has three levels ($i = 1, 2, 3$) and Factor B has two levels ($j = 1, 2$).

- (a) Construct contrasts for testing the differences in the levels of Factor A such that the sums of squares for the contrasts would sum to the total sum of squares for Factor A.
 - (b) Write the design matrix using sum to zero restrictions.
 - (c) Write out a basis set of estimable functions.
 - (d) Is $\alpha_1 - 2\alpha_2 + \alpha_3$ estimable? Explain.
2. (10 Points) When would Type II and Type III Sums of Squares be the same, but differ from the Type I Sum of Squares?

3. (10 points) Derive the least squares estimators for β_0 and β_1 for simple linear regression, $y_i = \beta_0 + \beta_1 x_i + \varepsilon_i$ (do not use matrix form).
4. (40 points) Various races are run on the Scottish hills. For each race, the record time (in seconds), the distance (in miles), and the climb (in feet) were recorded. The following output data, regression equation, and plots were produced by predicting time from distance and climb.
 - a. (10 points) State the assumptions that are necessary for this multiple regression. For each assumption, state whether it appears to be true from the following output or whether it's not possible to assess it from the output.
 - b. (5 points) The value of one of the parameter estimates is 0.66 (0.66289 in the output). Interpret this value.
 - c. (4 points) State and interpret the value of R-squared.
 - d. (8 points) Identify high leverage points. State evidence to show that they are high leverage.
 - e. (8 points) Identify high influence points. State evidence to show that they are high influence.
 - f. (5 points) Based on the information you have, do you think that this regression equation correctly fits the model? If yes, state evidence. If no, suggest how the model might be modified.
